

Mitra: 3Dshapes Analysis

Two datasets are being compared:

1. "(3,4)": A symbolic dataset with 3 attributes, 4 values each
2. "3dshapes": A visual dataset also with 3 attributes, 4 values each

All changes made:

evaluate_metrics.ipynb ->

- Generated results under compositionality scores: specifically topsim and topsim over time for 3dshapes

analysis_3ds_zero_shot.ipynb ->

- Ran the analysis on "Compositionality - Topsim"
- Added interpretation

analysis_zero_shot_qualitative.ipynb -> The whole notebook except for the last cell

- Still, had no access to the test interactions, so the results in the notebook are only from the 3dshapes
- Did not get to adapt the code for the last cell to generate the tables in Appendix of zero-shot paper, but will add my intuition on how the structure of concepts communicated for these two types of datasets differ
