

Mitra: 3Dshapes Analysis

Two datasets are being compared:

1. "(3,4)": A symbolic dataset with 3 attributes, 4 values each
2. "3dshapes": A visual dataset also with 3 attributes, 4 values each

All changes made:

evaluate_metrics.ipynb ->

- Generated results under compositionality scores: specifically topsim and topsim over time for 3dshapes

analysis_3ds_zero_shot.ipynb ->

- Ran the analysis on "Compositionality - Topsim"
- Added interpretation

analysis_zero_shot_qualitative.ipynb -> The whole notebook except for the last cell

- Added interpretation for message reuse and novelty rates
- The results in the notebook are only from the 3dshapes dataset, I made the comparison to D(3,4) only using the reported results in the repository and the zero-shot paper.
- Did not get to adapt the code for the last cell to generate the tables in Appendix of zero-shot paper, but printed out samples of concepts communicated in both datasets to see the differences between the t_{fixed} and t_{objects} . In the end, I added my intuition on how the structure of concepts communicated for these two types of datasets differ.
